Autonomous Units for Communication-based Dynamic Scheduling

Melanie Luderer International Graduate School for Dynamics in Logistics Karsten Hölscher Collaborative Research Centre 637 Peter Knirsch Bremen Research Cluster for Dynamics in Logistics

Theoretical Computer Science, University of Bremen

30. August 2007

Overview

- Autonomy in logistics
- Planning package transportation
- Transport networks
- Autonomous graph transformation units

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

- Sample negotiation
- Conclusion

Autonomy in Logistics

- Dynamics in logistics needs a paradigm shift
- Autonomy instead of centralized control: Passing control capabilities to the logistic objects
- Formal framework for modelling autonomous behaviour: Autonomous graph transformation units

Communication-based approach

Planning Package Transportation

- Packages have to be transported from one consolidation point to another
- Trucks with fixed routes and timetables
- Routes of packages have been planned according to truck timetables
- Which of the waiting packages are actually transported should be scheduled according to their own constraints
- ⇒ Market-based approach: Negotiation between packages and truck based on payment of transport rates

Transport Networks

- Road map modelled as a graph
- Trucks and packages are so called autonomous units represented as nodes
- Tour nodes represent tour sections
- Graph transformation rules for offers and replies

Autonomous Graph Transformation Units

Graph transformation

- A graph represents an environment
- Rule application on a graph realizes changes in environment
- Yielding a formal operational semantics including parallelism, concurrency and an inductive proof principle

Autonomous transformation unit

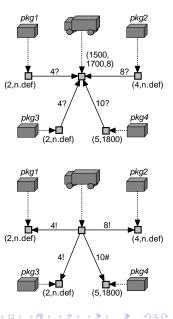

- Rule-based instantiation of the idea of an agent in a multi-agent system
- Autonomy: Next action is based on nondeterministic selection of a rule locally within each unit (rather than on control from outside the unit)

Sample Negotiation (1)

- Packages arriving at consolidation points are queued according to their arrival time
- Each package makes an offer for transportation to the desired truck Transport rate:

weight of package * transport time

 Truck scans the offers respecting the queue order, accepts as many offers as its capacity allows and rejects the rest

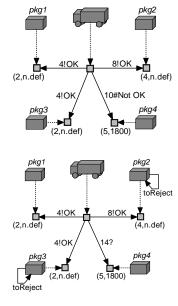

Sample Negotiation (2)

- Each package answers to acceptance/rejection of offer
- If all packages accept decision by truck

Transport schedule can be fixed

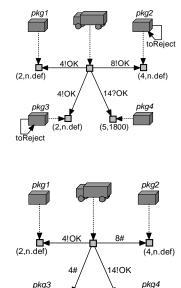

Missing amount compared to full truckload + 1 for every previously accepted and now rejected package

Sample Negotiation (3)

 If the respective packages accept the new transport rates

∜

(2.n.def)

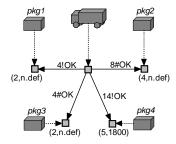

< E

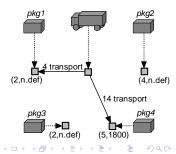

(5.

Truck issues new transport decision

Sample Negotiation (4)

 The now rejected packages answer to the new decision

Sample Negotiation (5)

- If a now rejected package disagrees with new situation a further negotiation starts
- From now on the new transport rate is calculated as before + 1 for every round of negotiations
- No endless negotiation
 - Package has only a fixed amount at its disposal

 Alternatively restrict the number of rounds of negotiations

Conclusion

Results

- Communicating autonomous units can model alternatives for transport scheduling
- Formal framework allows to prove properties of the modelled system

Future work

- Additional factors for negotiation process
 - customer retention
 - transhipment costs
 - competition between logistic companies
- Simulate and compare various negotiation concepts
